

## SOLVE LINEAR SYSTEMS USING ELIMINATION

1. Solve each linear system.

a)  $x + 3y = 5$  ①  
 $5x + 2y = 12$  ②

Multiply one of the equations: ① $\times 5$ <span style="float: right;"><math>5(x + 3y = 5)</math> <math>5x + 15y = 25</math> ③</span>		
Add or subtract the equations to eliminate one of the variables and then solve: (2) & (3)	Solve for the other variable: Sub $y=1$ into ①	Solution:
$  \begin{array}{r}  5x + 2y = 12 \\  - (5x + 15y = 25) \\  \hline  \cancel{0} [2y - 15y] = [12 - 25] \\  -13y = -13 \\  \frac{-13y}{-13} = \frac{-13}{-13} \\  \boxed{y = 1}  \end{array}  $	$  \begin{array}{l}  x + 3y = 5 \\  x + 3(1) = 5 \\  x + 3 = 5 \\  x = 5 - 3 \\  \boxed{x = 2}  \end{array}  $	$  \begin{array}{l}  \therefore \text{POI} \\  \text{is} \\  (2, 1)  \end{array}  $

b)  $3x + 2y = 2$  ①  
 $x + 4y = 14$  ②

Multiply one of the equations: ② $\times 3$ <span style="float: right;"><math>3(x + 4y = 14)</math> <math>3x + 12y = 42</math> ③</span>		
Add or subtract the equations to eliminate one of the variables and then solve: (1) & (3)	Solve for the other variable: Sub $y=4$ into ②	Solution:
$  \begin{array}{r}  3x + 2y = 2 \\  - (3x + 12y = 42) \\  \hline  \cancel{0} [2y - 12y] = [2 - 42] \\  -10y = -40 \\  \frac{-10y}{-10} = \frac{-40}{-10} \\  \boxed{y = 4}  \end{array}  $	$  \begin{array}{l}  x + 4y = 14 \\  x + 4(4) = 14 \\  x + 16 = 14 \\  x = 14 - 16 \\  \boxed{x = -2}  \end{array}  $	$  \begin{array}{l}  \therefore \text{POI} \\  \text{is} \\  (-2, 4)  \end{array}  $

$$\begin{aligned} \text{c) } 3x - y &= 2 & \textcircled{1} \\ 2x + 3y &= 16 & \textcircled{2} \end{aligned}$$

Multiply one of the equations: $\textcircled{1} \times 3$ <span style="margin-left: 50px;"><math>3(3x - y = 2)</math> <math>9x - 3y = 6</math> <math>\textcircled{3}</math></span>		
Add or subtract the equations to eliminate one of the variables and then solve: $\textcircled{2} \div \textcircled{3}$	Solve for the other variable: Sub $x=2$ into $\textcircled{1}$	Solution:
$\begin{array}{r} 2x + 3y = 16 \\ + 9x - 3y = 6 \\ \hline [2x + 9x] \quad \cancel{\phi} = [16 + 6] \\ 11x = 22 \\ \frac{11x}{11} = \frac{22}{11} \\ \boxed{x = 2} \end{array}$	$\begin{array}{l} 3x - y = 2 \\ 3(2) - y = 2 \\ 6 - y = 2 \\ 6 - 2 = y \\ \boxed{4 = y} \end{array}$	$\therefore \text{PoI is } (2, 4)$

2. A local band called Rawk held a concert where 5000 people attended with  $x$  representing the number of lower bowl tickets and  $y$  representing the number of upper bowl seating tickets.

This is represented by the equation:  $x + y = 5000$   $\textcircled{1}$

The lower bowl tickets cost \$60 while the upper bowl tickets cost \$40. Ticket sales totaled \$264 000.

This is represented by the equation:  $60x + 40y = 264\,000$   $\textcircled{2}$

How many lower bowl and upper bowl tickets were sold?

$$\textcircled{1} \times 60 \quad 60(x + y = 5000)$$

$$60x + 60y = 300\,000 \quad \textcircled{3}$$

$$\textcircled{2} \div \textcircled{3}$$

$$\begin{array}{r} 60x + 40y = 264\,000 \\ - 60x + 60y = 300\,000 \\ \hline \end{array}$$

$$\cancel{\phi} [40y - 60y] = [264\,000 - 300\,000]$$

$$\begin{array}{r} -20y = -36\,000 \\ \frac{-20y}{-20} = \frac{-36\,000}{-20} \end{array}$$

$$y = 1800$$

$$\text{Sub } y = 1800 \text{ into } \textcircled{1}$$

$$x + y = 5000$$

$$x + 1800 = 5000$$

$$x = 5000 - 1800$$

$$x = 3200$$

$$\text{PoI} = (3200, 1800)$$

$\uparrow$  lower       $\uparrow$  upper

$\therefore$  They sold 3200 lower bowl & 1800 upper bowl tickets.
